

S5b Figure. Protein-level training response across age groups. Per-subject  $\log_2$  change (Post – Pre) for the proteins reaching FDR < 0.05 with training in younger adults, across the paired younger and older participants. Rows are grouped by the direction of the younger-adult response and annotated with whether the older-adult response shares that sign; grey cells are proteins not quantified in that participant. The right-hand panel gives the most enriched over-representation terms for the increased and for the decreased sets.
