

No parent trial spans both age groups, so adjusting for cohort removes the aging signal

S9 Figure. Cohort structure and the effect of adjusting for it. (A) The four models, from the most detailed cohort grouping to the simplest. (B) Proteins detected per contrast under each model. (C) Standard errors, (D) fold-change agreement and (E) aging p-value distributions behind those counts. All four designs are estimable (full rank); results are in S10 Table.
